Functions

Mirko has written the following function:

```
function fun: longint;
                                                                  var
int fun() {
                                                                    ret: longint;
 int ret = 0;
                                                                    a, b, ... , y, z: longint;
  for (int a = X1; a \le Y1; ++a)
                                                                  begin
    for (int b = X2; b <= Y2; ++b)
                                                                    ret := 0;
                                                                    for a := X1 to Y1 do
        for (int \langle N-th \rangle = XN; \langle N-th \rangle \langle = YN; ++\langle N-th \rangle)
                                                                     for b := X2 to Y2 do
          ret = (ret + 1) % 1000000007;
                                                                          for \langle N-th \rangle := XN to YN do
 return ret;
                                                                             ret := (ret + 1) mod 1000000007;
                                                                    fun := ret;
```

<N-th>denotes the Nth lowercase letter of the English alphabet. Each X_i and Y_i denotes either a positive integer less than or equal to 100 000 or a name of a variable that some outer loop iterates over. For example, X3 can be either a, b, or an integer literal. At least one of X_i and Y_i will be an integer literal (i.e. not a variable name) for every i. Compute the return value of the function.

Input

The first line of input contains the positive integer N (1 \leq N \leq 26). For the next N lines, the ith line contains X_i and Y_i, separated with a space. If X_i and Y_i are both integer literals, then X_i \leq Y_i

Output

The first and only line of output must contain the return value of the function.

Sample input

Sample output

2	5	
12		
a 3		
3	10	
23		
12		
1 a		
3	11	
12		
a 3		
1 b
